# 1.5 — Demand ECON 306 • Microeconomic Analysis • Fall 2022 Ryan Safner Associate Professor of Economics safner@hood.edu ryansafner/microF22

Signature Market Strategy and S

#### Outline

#### Income Effect

**<u>Digression: Measuring Change</u>** 

**Cross-Price Effects** 

#### The consumer's Problem: Review

- We now can explore the dynamics of how individuals optimally respond to changes in their constraints
- We know the **(static)** problem is:
- 1. Choose: < a consumption bundle >
- 2. In order to maximize: < utility >
- 3. Subject to: < income and market prices >

 A consumer's demand (for good x) depends on current prices & income:

$$q^D_x = q^D_x(m,p_x,p_y)$$

• How does demand (for x) change?

 A consumer's demand (for good x) depends on current prices & income:

$$q^D_x = q^D_x(m,p_x,p_y)$$

• How does demand (for x) change?

1. Income effects  $\left(\frac{\Delta q^D_x}{\Delta m}\right)$ : how  $q^D_x$  changes with changes in income

 A consumer's demand (for good x) depends on current prices & income:

$$q^D_x = q^D_x(m,p_x,p_y)$$

• How does demand (for x) change?

1. Income effects  $\left(\frac{\Delta q_x^D}{\Delta m}\right)$ : how  $q_x^D$  changes with changes in income 2. Cross-price effects  $\left(\frac{\Delta q_x^D}{\Delta p_y}\right)$ : how  $q_x^D$  changes

with changes in prices of *other* goods (e.g. y)

 A consumer's demand (for good x) depends on current prices & income:

$$q^D_x = q^D_x(m,p_x,p_y)$$

- How does demand (for x) change?
- 1. Income effects  $\left(\frac{\Delta q_x^D}{\Delta m}\right)$ : how  $q_x^D$  changes with changes in income 2. Cross-price effects  $\left(\frac{\Delta q_x^D}{\Delta p_y}\right)$ : how  $q_x^D$  changes with changes in prices of *other* goods (e.g. y) 3. (Own) Price effects  $\left(\frac{\Delta q_x^D}{\Delta p_x}\right)$ : how  $q_x^D$  changes with changes in price (of x)

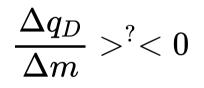

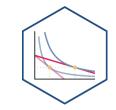

#### **Income Effect**

#### **Income Effect**

 Income effect: change in optimal consumption of a good associated with a change in (nominal) income, holding relative prices constant

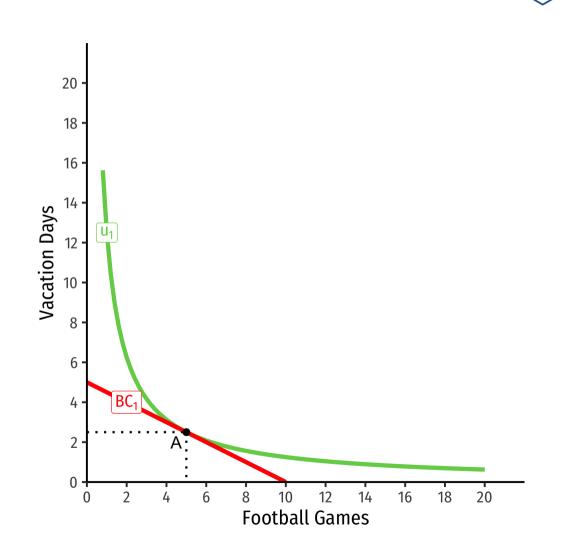

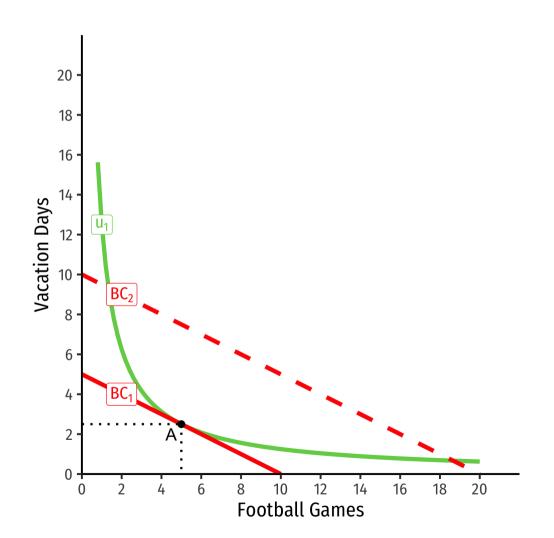

#### Income Effect (Normal)

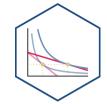

• Consider football tickets and vacation days

#### Income Effect (Normal)

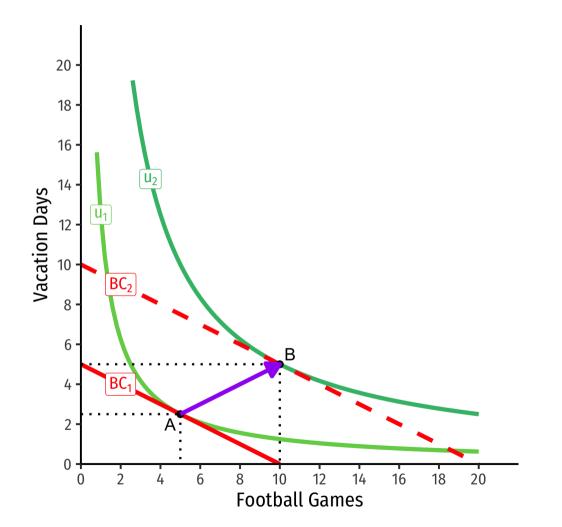

- Consider football tickets and vacation days
- Suppose income (m) increases

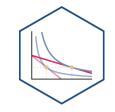

#### Income Effect (Normal)

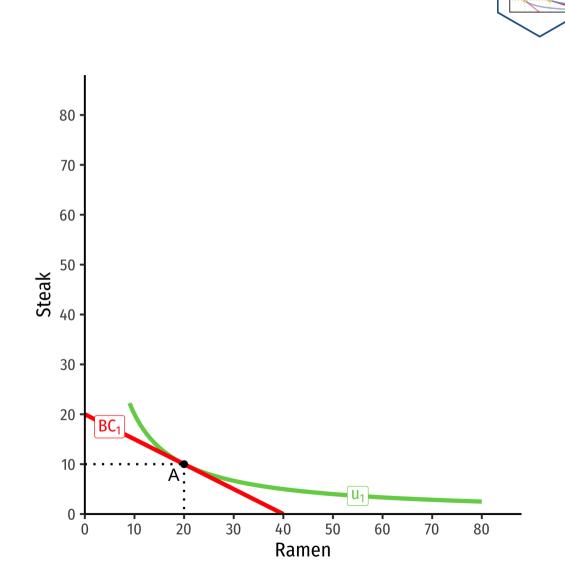

- Consider football tickets and vacation days
- Suppose income (m) increases
- At new optimum (B), consumes more of both
- Then both goods are **normal goods**

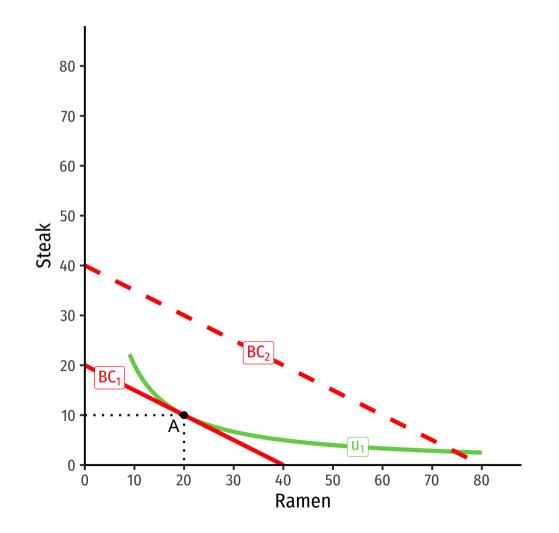

#### **Income Effect (Inferior)**

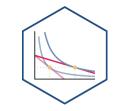

• Consider ramen and steak

#### **Income Effect (Inferior)**

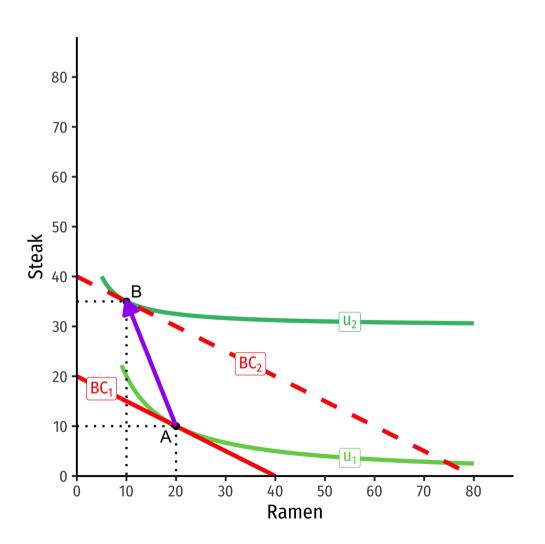

- Consider ramen and steak
- Suppose income (m) increases

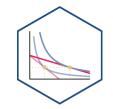

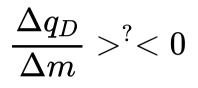

#### **Income Effect (Inferior)**

- Consider ramen and steak
- Suppose income (m) increases
- At new optimum (B), consumes more steak, less ramen
- Steak is a normal good, ramen is an inferior good

#### **Income Effect**

- Normal goods: consumption increases with more income (and vice versa)
- Inferior goods: consumption decreases with more income (and vice versa)

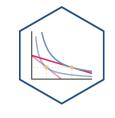

### **Digression: Measuring Change**

#### **Quantifying Changes I**

- Several ways we can talk about how a measure **changes** over time, from time  $t_1 
  ightarrow t_2$
- Difference  $(\Delta)$ : the difference between the value at time  $t_1$  and time  $t_2$

$$\Delta t = t_2 - t_1$$

#### **Quantifying Changes II**

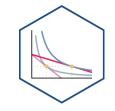

- Several ways we can talk about how a measure **changes** over time, from time  $t_1 
  ightarrow t_2$
- Difference  $(\Delta)$ : the difference between the value at time  $t_1$  and time  $t_2$

$$\Delta t = t_2 - t_1$$

• **Relative Difference**: the difference expressed **in terms of the original value** 

$$rac{\Delta t}{t_1} = rac{t_2-t_1}{t_1}$$

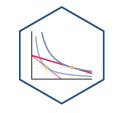

this becomes a proportion (a decimal)

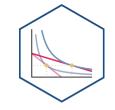

#### **Quantifying Changes III**

• Percentage Change (Growth Rate): relative difference expressed as a percentage

$$egin{aligned} \%\Delta &= rac{\Delta t}{t_1} imes 100\% \ &= rac{t_2 - t_1}{t_1} imes 100\% \end{aligned}$$

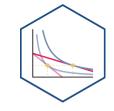

#### A Simple Example Growth Rate

**Example**: A country's GDP is \$100bn in 2022, and \$120bn in 2021 Calculate the country's GDP growth rate for 2022:

#### Elasticity, in General

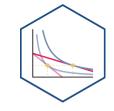

$$\epsilon_{y,x} = rac{\% \Delta y}{\% \Delta x} = rac{rac{\Delta y}{y}}{rac{\Delta x}{x}}$$

• An elasticity between any two variables y and x describes the responsiveness of a variable (y) to a change in another (x).

 $\circ$  (relative change in y) over (relative change in x)

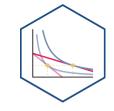

#### Elasticity, in General

$$\epsilon_{y,x} = rac{\% \Delta y}{\% \Delta x} = rac{rac{\Delta y}{y}}{rac{\Delta x}{x}}$$

- An elasticity between any two variables y and x describes the responsiveness of a variable (y) to a change in another (x).
  - $\circ$  (relative change in y) over (relative change in x)
- Interpretation:  $\epsilon_{y,x} =$  the *percentage change* in y from a 1% change in x

#### Elasticity, in General

$$\epsilon_{y,x} = rac{\% \Delta y}{\% \Delta x} = rac{rac{\Delta y}{y}}{rac{\Delta x}{x}}$$

- An elasticity between any two variables y and x describes the responsiveness of a variable (y) to a change in another (x).
  - $\circ$  (relative change in y) over (relative change in x)
- Interpretation:  $\epsilon_{y,x} =$  the *percentage change* in y from a 1% change in x
- Unitless: easy comparisons between any 2 variables
  - e.g. crime rates and police, GDP and gov't spending, inequality and corruption

$$\epsilon_{q,m} = rac{\%\Delta q_D}{\%\Delta m}$$

• The income elasticity of demand measures how much quantity demanded  $(q_D)$  changes in response to a change in income (m)

$$\epsilon_{q,m} = rac{\%\Delta q_D}{\%\Delta m}$$

• If  $\epsilon_{q,m}$  is **negative**: an **inferior** good

$$\epsilon_{q,m} = rac{\%\Delta q_D}{\%\Delta m}$$

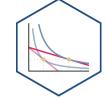

- If  $\epsilon_{q,m}$  is **negative**: an **inferior** good
- If  $\epsilon_{q,m}$  is **positive**: a **normal** good

$$\epsilon_{q,m} = rac{\%\Delta q_D}{\%\Delta m}$$

- If  $\epsilon_{q,m}$  is **negative**: an **inferior** good
- If  $\epsilon_{q,m}$  is **positive**: a **normal** good
- Two subtypes of normal goods:
  - $\circ$  Necessity:  $0 \leq \epsilon_{q,m} \leq 1$ 
    - $\uparrow$  quantity demanded as  $\uparrow\uparrow$  income (water, clothing)

$$\epsilon_{q,m} = rac{\%\Delta q_D}{\%\Delta m}$$

- If  $\epsilon_{q,m}$  is **negative**: an **inferior** good
- If  $\epsilon_{q,m}$  is **positive**: a **normal** good
- Two subtypes of normal goods:
  - $\circ$  Necessity:  $0 \leq \epsilon_{q,m} \leq 1$ 
    - $\uparrow$  quantity demanded as  $\uparrow\uparrow$  income (water, clothing)
  - $\circ\,$  Luxury:  $\epsilon_{q,m}>1$ 
    - $\uparrow\uparrow$  quantity demanded as  $\uparrow$  income (jewelry, vacations)

• For now, we can **calculate** the income elasticity of demand simply by calculating the **relative changes**:

$$rac{\%\Delta q}{\%\Delta m} = rac{\left(rac{\Delta q}{q_1}
ight)}{\left(rac{\Delta m}{m_1}
ight)}$$

• We'll use some fancier methods when we talk about the only elasticity you've probably seen before: *price* elasticity of demand

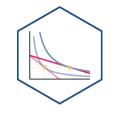

#### **Income Elasticity of Demand: Example**

**Example**: You can spend your income on golf and pancakes. Green fees at a local golf course are \$10 per round and pancake mix is \$2 per box. When your income is \$100, you buy 5 boxes of pancake mix and 9 rounds of golf. When your income increases to \$120, you buy 10 boxes of pancake mix and 10 rounds of golf.

1. What type of good is golf (inferior, necessity, luxury)?

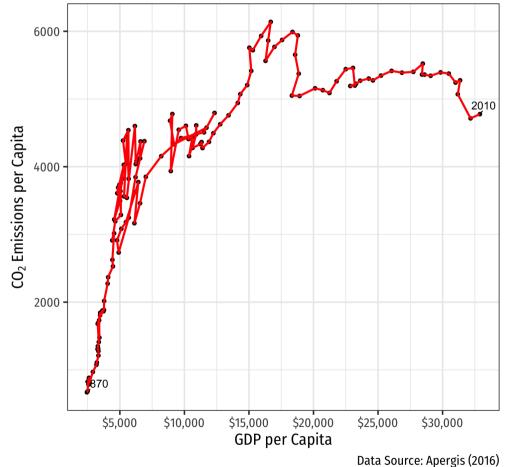

2. What type of good are pancakes (inferior, necessity, or luxury)?

#### **Income Effects: Example**

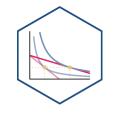

# **Example**: Is the environment a normal good?

Environmental Kuznets Curve for U.S. 1870-2010

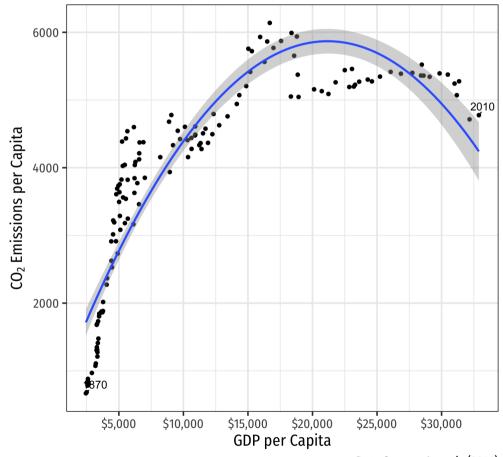

#### **Income Effects: Example**

# **Example**: Is the environment a normal good?

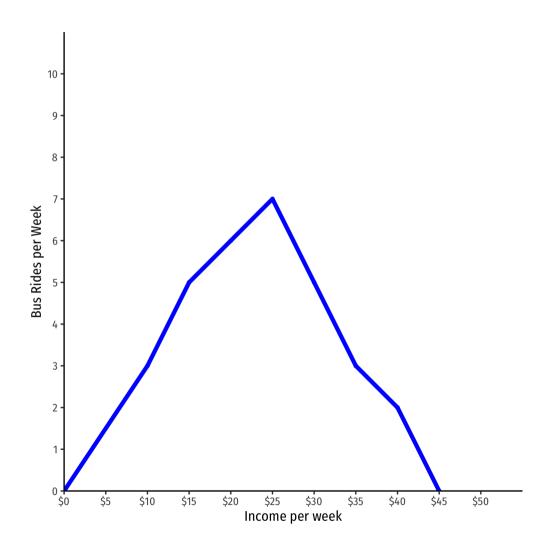

Environmental Kuznets Curve for U.S. 1870-2010

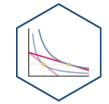

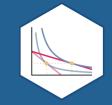

Data Source: Apergis (2016)

#### **Engel Curves**

- Engel curve visualizes income effects: shows how consumption of *one* good changes when income increases
- When positively sloped: normal good
- When negatively sloped: inferior good

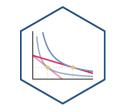

#### **Cross-Price Effects**

#### **Cross-Price Effects**

 Cross-price effect: change in optimal consumption of a good associated with a change in price of *another* good income, holding the good's *own* price (and income) constant

$$rac{\Delta q_x}{\Delta p_y}>^?<0$$

#### **Cross-Price Elasticity of Demand I**

• The cross-price elasticity of demand

measures how much quantity demanded of one good  $(q_x)$  changes in response to a change in price of *another* good  $(p_y)$ 

$$\epsilon_{q_x,p_y} = rac{\%\Delta q_x}{\%\Delta p_y}$$

#### **Cross-Price Elasticity of Demand I**

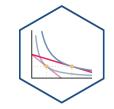

• The cross-price elasticity of demand

measures how much quantity demanded of one good  $(q_x)$  changes in response to a change in price of *another* good  $(p_y)$ 

$$\epsilon_{q_x,p_y} = rac{\%\Delta q_x}{\%\Delta p_y} = rac{rac{\Delta q_x}{q_x}}{rac{\Delta p_y}{p_y}}$$

#### **Cross-Price Elasticity of Demand II**

$$\epsilon_{q_x,p_y} = rac{\%\Delta q_x}{\%\Delta p_y}$$

- If  $\epsilon_{q_x,p_y}$  is *positive*: goods x and y are **substitutes**
- An rise (fall) in price of y causes more (less) consumption of x
  - $\circ~$  Consumption of x moves in same direction as price of y

#### **Cross-Price Elasticity of Demand III**

$$\epsilon_{q_x,p_y} = rac{\%\Delta q_x}{\%\Delta p_y}$$

- If  $\epsilon_{q_x,p_y}$  is *negative*: goods x and y are **complements**
- Goods x and y consumed in a *bundle*, concern about overall price of *bundle*
- A rise (fall) in price of y causes less (more) consumption of x
  - Consumption of x moves in opposite
     direction as price of y

#### **Cross-Price Elasticity: Example I**

**Example**: You can travel into the city every week on Lyft rides and Uber rides. When Lyft is \$20/ride, you ride 10 Uber rides. When Lyft raises prices to \$25/ride, you ride 15 Uber rides.

1. What is the relationship between these two goods?

2. What is the cross-price elasticity?
